# Normal incidence transmission ellipsometry of anisotropic layers 

John Lekner<br>Department of Physics. Victoria University of Wellington, Wellington, New Zealand

Received 21 January 1993. in final form 28 May 1993

#### Abstract

We consider various ellipsometric arrangements, consisting of polarizer, sample and analyser, with a compensator or polarization modulator inserted before or after the sample. These configurations enable the determination of the real and complex parts of the ratio of two basic transmission amplitudes. The polarizer-sample-analyser configuration can determine the absolute square and the real part of the ratio of the two basic transmission amplitudes. The transmission amplitudes are obtained by methods previously developed by the author for uniaxial crystals. The method is extended to include biaxial crystals. Transmission properties of free and supported anisotropic layers are discussed.

## 1. Introduction

In a recent paper (Lekner 1992) we have shown that the normal incidence reflection and transmission properties of a uniaxial crystal layer are contained in two reflection and two transmission amplitudes, $r_{0}, r_{\mathrm{c}}$ and $t_{\mathrm{o}}, t_{\mathrm{c}}$. These were found by a $2 \times 2$ matrix method. This is in contrast to the situation at oblique incidence, where four reffection and four transmission coefficients are needed, and where the usual approach is via a $4 \times 4$ matrix formalism. (See, for example, Wöhler et al 1988 or Eidner et al 1989 for recent work and further references.) Here we give the theory of what is measured in normal incidence transmission ellipsometry, for various experimental arrangements. Normal incidence transmission ellipsometry can be considered to be complementary to the technique of reflectance anisotropy, in which the difference between normal incidence reflectances is measured for light polarized along the two principal axes of the surface (Acher and Drévillon 1992).

Section 2 summarizes the results for transmission by uniaxial layers, and the appendix extends these results to biaxial layers. Sections 3 to 7 analyse five ellipsometer configurations. In section 8 we give some properties of the measured transmission amplitude ratio for a single anisotropic layer (e.g. mica in air), and for an anisotropic layer on an isotropic substrate.

## 2. Normal-incidence transmission by a uniaxial layer

A plane monochromatic wave normally incident onto a uniaxial crystal splits into two components which travel in the crystal as the plane waves

$$
\begin{equation*}
E_{\mathrm{o}} \operatorname{expi}\left(k_{\mathrm{o}} z-\omega t\right) \quad E_{\mathrm{e}} \exp \mathrm{i}\left(k_{\mathrm{e}} z-\omega t\right) \tag{1}
\end{equation*}
$$

The subscripts o and e stand for ordinary and extraordinary. $E_{\mathrm{o}}$ and $E_{\mathrm{c}}$ are electric field vectors, and are orthogonal for normal incidence (but not in general: see Lekner 1991, equation (29)). The wavevector magnitudes $k_{o}$ and $k_{e}$ are given by

$$
\begin{equation*}
k_{\mathrm{o}}=n_{\mathrm{o}} \omega / c \quad k_{\mathrm{e}}=k_{\mathrm{o}} n_{\mathrm{e}} /\left(\varepsilon_{\mathrm{o}} \sin ^{2} \psi+\varepsilon_{\mathrm{e}} \cos ^{2} \psi\right)^{1 / 2} \tag{2}
\end{equation*}
$$

where $n_{o}$ and $n_{e}$ are the ordinary and extraordinary refractive indices, $\varepsilon_{o}=n_{o}^{2}$ and $\varepsilon_{c}=n_{e}^{2}$ are the corresponding dielectric constants, and $\psi$ is the angle between the optic axis $c$ and the normal to the crystal. (The inward normal $n=(0,0,1)$ coincides with the $z$ axis.) The ordinary electric field vector $E_{0}$ is perpendicular to $n$, being along the $n \times c$ direction. The extraordinary electric field vector $E_{\mathrm{e}}$ is perpendicuiar $E_{\mathrm{o}}$, but is not perpendicular to $n$ unless $\psi$ is zero or $90^{\circ}$. Nevertheless one can designate by o and e two perpendicular directions in the plane normal to $n$, the first being $E_{0}$, and the second the projection of $E_{\mathrm{e}}$ onto this plane. The latter direction coincides with that of $E_{\mathrm{o}} \times n$.

Now consider a crystal plate of thickness $d$, between the medium of incidence of refractive index $n_{1}$, and the substrate of index $n_{2}$. It is shown in Lekner 1992 that the transmission properties are characterized by two transmission amplitudes, $t_{0}$ and $t_{e}$, corresponding to incident polarization along the o and e directions, respectively. These are given by

$$
\begin{align*}
& t^{\circ}=\frac{t_{1}^{\circ} t_{2}^{\circ} \mathrm{e}^{\mathrm{i} k_{\mathrm{o}} d}}{1+r_{1}^{\circ} r_{2}^{\circ} \mathrm{e}^{2 \mathrm{i} k_{o} d}}  \tag{3}\\
& t_{1}^{\circ}=1+r_{1}^{\circ}=\frac{2 k_{1}}{k_{1}+k_{\mathrm{o}}} \quad t_{2}^{\circ}=1+r_{2}^{\circ}=\frac{2 k_{o}}{k_{\mathrm{o}}+k_{2}} \tag{4}
\end{align*}
$$

and a similar set of formulae for $t_{\mathrm{e}}$, with $k_{\mathrm{e}}$ replacing $k_{\mathrm{o}}$. The wavevector magnitudes $k_{1}$ and $k_{2}$ are $n_{1} \omega / c$ and $n_{2} \omega / c$, respectively. The coefficients $r_{1}^{\circ}$ and $t_{1}^{\circ}$ are the Fresnel reflection and transmission amplitudes for the interface between media of indices $n_{1}$ and $n_{0}$, and likewise $r_{2}^{o}$ and $t_{2}^{\circ}$ are those for the interface between $n_{0}$ and $n_{2}$. Thus (30) is identical to the transmission amplitude for an isotropic slab of index $n_{0}$, while the formula for $t_{e}$ is the same as for an isotropic slab of index

$$
\begin{equation*}
\frac{n_{\mathrm{o}} n_{\mathrm{c}}}{\left[\left(n_{\mathrm{o}} \sin \psi\right)^{2}+\left(n_{\mathrm{e}} \cos \psi\right)^{2}\right]^{1 / 2}} \tag{5}
\end{equation*}
$$

When the incident wave is linearly polarized with its electric field vector at angle $\phi$ to the $E_{0}$ direction, the transmission amplitudes

$$
\begin{equation*}
t=t_{0} \cos ^{2} \phi+t_{\mathrm{e}} \sin ^{2} \phi \quad t^{\prime}=\left(t_{\mathrm{o}}-t_{\mathrm{e}}\right) \cos \phi \sin \phi \tag{6}
\end{equation*}
$$

give the components of the transmitted field along and perpendicular to the incident field direction.

The above formulae are for uniaxial crystals. In the appendix we show that results of the same form as equations (3), (4) and (6) hold also for biaxial crystals, with $k_{\circ}$ and $k_{\mathrm{e}}$ replaced by $k_{+}$and $k_{-}$, the positive square roots of a quadratic equation for $k^{2}$, equation (A5). The directions o and e are simultaneously to be replaced by the directions $\mathrm{e}^{+}$and $\mathrm{e}^{-}$of the projections of the electric fields $E^{+}$and $E^{-}$onto the reflecting plane. In the body of this paper we will continue to use the uniaxial o and e notation for convenience, with the understanding that the results apply (with the above substitutions) to the biaxial case also.

To calculate the output of a transmission ellipsometer we need an extension of the results of Lekner (1992) to the case where the substrate is of finite thickness $d_{2}$, since the usual experimental situation is that the light originates and ends in the same ambient medium of index $n_{1}$ (usually air or vacuum). Consider first the case of light incident with polarization along the o direction. The reflection-transmission problem is then the same as for isotropic media with indices $n_{1}, n_{0}, n_{2}, n_{1}$. The reflection and transmission amplitudes $r_{0}$ and $t_{\mathrm{o}}$ for this system can be found by matrix methods. From Lekner (1987), section 12.2, we find

$$
\left.\begin{array}{l}
r_{\mathrm{o}}=\frac{k_{1}^{2} m_{12}+m_{21}+\mathrm{i} k_{1}\left(m_{22}-m_{11}\right)}{k_{1}^{2} m_{12}}-m_{21}+\mathrm{i} k_{1}\left(m_{22}+m_{11}\right)  \tag{7}\\
t_{\mathrm{o}}=\frac{2 \mathrm{i} k_{1}}{k_{1}^{2} m_{12}-m_{21}+\mathrm{i} k_{1}\left(m_{22}+m_{11}\right)}
\end{array}\right\}
$$

where the matrix elements $m_{i j}$ are given by

$$
\begin{align*}
& m_{11}=c_{2} c_{\mathrm{o}}-\frac{k_{\mathrm{o}}}{k_{2}} s_{2} s_{\mathrm{o}}  \tag{8}\\
& m_{12}=\frac{c_{2} s_{\mathrm{o}}}{k_{\mathrm{o}}}+\frac{s_{2} c_{0}}{k_{2}} \\
& m_{21}=-k_{2} s_{2} c_{\mathrm{o}}-k_{\mathrm{o}} s_{\mathrm{o}} c_{2} \\
& m_{22}=c_{2} c_{\mathrm{o}}-\frac{k_{2}}{k_{\mathrm{o}}} s_{2} s_{\mathrm{o}} \\
& c_{\mathrm{o}}=\cos k_{\mathrm{o}} d \quad s_{\mathrm{o}}=\sin k_{\mathrm{o}} d \quad c_{2}=\cos k_{2} d_{2} \quad s_{2}=\sin k_{2} d_{2} .
\end{align*}
$$

It follows from the structure of (7) and (8) that $t_{0}$ is the same whether the layer of index $n_{2}$ comes before or after the anisotropic layer, in accord with the general theorem of section 2-1 of Lekner 1987, equation (2.14).

For incident polarization along the e direction, corresponding results are obtained by substituting $e$ for $o$ in the subscripts of the formulae (7) and (8). It is clear from formulae (3) and (7) that the phase difference between the transmitted $o$ and $e$ waves is not simply ( $k_{\mathrm{o}}-k_{\mathrm{e}}$ )d, as is sometimes assumed (see for example Born and Wolf (1965), section 14.4.3). As explained in Holmes (1964) and Lekner (1992), the latter expression does not allow for multiple reflections inside the crystal plate. Holmes considered the case where the principal dielectric axes of the unsupported plate are aligned parallel and perpendicular to the plate normal. The phase difference given in equation (53) of Lekner (1992) is for arbitrary orientation of the optic axis of an unsupported uniaxial plate, and the appendix of the present paper shows how this may be generalized to biaxial plates, again of arbitrary orientation. The experimental aspects of ellipsometry with non-ideal compensators have been considered by Archer and Shank (1967) and Yolken et al (1967). See also Azzam and Basharta (1987), section 5.2.1.2.

## 3. Polarizer-sample-analyser

Figure 1 shows this arrangement, with the anisotropic layer on a substrate of index $n_{2}$. For this case, and also when the isotropic layer precedes the anisotropic layer, $t_{0}$ is given by formulae (7) and (8), and $t_{\mathrm{e}}$ by the same formulae with $k_{0}$ replaced by $k_{\mathrm{e}}$. If

Figure 1. The polarizer-sample-analyser arrangement. The angles $P$ and $A$ give the directions of the easy axes of the polarizer and analyser, relative to the o direction of the crystal.
the substrate is absent, $t_{0}$ is given by equations (3) and (4) with $k_{2}$ replaced by $k_{1}$, and $t_{\mathrm{e}}$ likewise, with $k_{0}$ replaced by $k_{\mathrm{e}}$. .

We consider the electric field amplitude, resolved along the $o$ and e directions of the crystal:

|  | along 0 | along e |
| :--- | :--- | :--- |
| after polarizer: | $\cos P$ | $\sin P$ |
| after sample: | $t_{0} \cos P$ | $t_{\mathrm{c}} \sin P$ |

After the analyser the amplitude is thus

$$
\begin{equation*}
t_{0} \cos P \cos A+t_{c} \sin P \sin A \tag{9}
\end{equation*}
$$

For an isotropic material we would have $t_{\mathrm{o}}=t_{\mathrm{e}}$, and hence the amplitude transmitted by the analyser proportional to $\cos (P-A)$, which is zero when the polarizer and analyser easy axes are at right angles. This is the crossed-polar configuration used in polarization microscopes (see for example Gribble and Hall 1985). When $A=P \pm 90^{\circ}$, formula (9) becomes

$$
\begin{equation*}
\pm\left(t_{\mathrm{e}}-t_{\mathrm{o}}\right) \cos P \sin P \tag{10}
\end{equation*}
$$

Thus the transmitted intensity is zero when the polarizer and analyser easy axes are at right angles, with one along the o direction and the other along the e direction. Extinction thus determines the o-e pair of axes, but does not distinguish between the $o$ and e directions.

The intensity, obtained as the absolute square of formula (9), is proportional to
$\left|t_{\mathrm{o}}\right|^{2} \cos ^{2} P \cos ^{2} A+2 \operatorname{Re}\left(t_{\mathrm{o}} t_{\mathrm{e}}^{*}\right) \cos P \cos A \sin P \sin A+\left|t_{\mathrm{e}}\right|^{2} \sin ^{2} P \sin ^{2} A$.
There are three unknowns: $\left|t_{\mathrm{o}}\right|,\left|t_{\mathrm{e}}\right|$, and the phase difference between $t_{\mathrm{o}}$ and $t_{\mathrm{c}}$. Three intensity measurements at different polarizer or analyser settings, plus an intensity measurement with the sample absent, are in principle sufficient to find the absolute magnitudes of the transmission amplitudes, and their relative phase.

The expression (9) for the final field amplitude was obtained by using the fundamental $t_{\mathrm{o}}$ and $t_{\mathrm{e}}$ transmission amplitudes, and resolving along the o and e directions. We can check that the same expression results on using formula (6): the field
transmitted by the sample has components along and perpendicular to the polarizer easy direction equal to

$$
\begin{equation*}
t_{\mathrm{o}} \cos ^{2} P+t_{e} \sin ^{2} P \quad\left(t_{\mathrm{o}}-t_{\mathrm{e}}\right) \cos P \sin P \tag{12}
\end{equation*}
$$

The field transmitted by the analyser is thus

$$
\begin{gather*}
\left(t_{\mathrm{o}} \cos ^{2} P+t_{\mathrm{e}} \sin ^{2} P\right) \cos (P-A)+\left(t_{\mathrm{o}}-t_{\mathrm{e}}\right) \cos P \sin P \sin (P-A) \\
=t_{\mathrm{o}} \cos P \cos A+t_{\mathrm{e}} \sin P \sin A \tag{13}
\end{gather*}
$$

in agreement with formula (9).

## 4. Polarizer-compensator-sample-analyser

We consider now the effect of inserting a compensator (also known as a waveplate, or a retarder) between the polarizer and the sample. The compensator is a crystal plate, or combination of plates, which produces a known phase difference between two orthogonal components of the transmitted electric field. We will call these orthogonal directions $\mathrm{o}^{\prime}$ and $\mathrm{e}^{\prime}$, and $C$ the angle between the $\mathrm{o}^{\prime}$ and o directions of compensator and sample (see figure 2).

We first resolve along the $o^{\prime}$ and $\mathrm{e}^{\prime}$ directions of the compensator. After the polarizer, the respective field components are $\cos (P-C)$ and $\sin (P-C)$. After the compensator the $o^{\prime}$ and $\mathrm{e}^{\prime}$ components of the electric field are $t_{\mathrm{o}}^{\prime} \cos (P-C)$ and $t_{\mathrm{e}}^{\prime} \sin (P-C)$, where $t_{0}^{\prime}$ and $t_{e}^{\prime}$ are the complex compensator transmission amplitudes for light polarized along the $o^{\prime}$ and $\mathrm{e}^{\prime}$ directions.

We now resolve along the $o$ and e directions of the crystal. The electric field components are

$$
\left.\begin{array}{l}
E_{\mathrm{o}}=t_{\mathrm{o}}^{\prime} \cos (P-C) \cos C-t_{\mathrm{e}}^{\prime} \sin (P-C) \sin C  \tag{14}\\
E_{\mathrm{e}}=t_{\mathrm{o}}^{\prime} \cos (P-C) \sin C+t_{\mathrm{e}}^{\prime} \sin (P-C) \cos C
\end{array}\right\}
$$

After transmission through the sample the electric field components along $O$ and $e$ are $t_{0} E_{\mathrm{o}}$ and $t_{\mathrm{e}} E_{\mathrm{e}}$, and after the analyser the final field is

$$
\begin{equation*}
t_{\mathrm{o}} E_{\mathrm{o}} \cos A+t_{\mathrm{e}} E_{\mathrm{e}} \sin A \tag{15}
\end{equation*}
$$

The intensity is proportional to the absolute square of this quantity. We consider the

Figure 2. The polarizer-compensator-sample-analyser transmission ellipsometer arrangement.
particular case of a null setting of the ellipsometer, in which the intensity is made zero (in practice minimized). The intensity will be zero when the real and imaginary parts of the equality

$$
\begin{equation*}
t_{\mathrm{o}} / t_{\mathrm{c}}=-\frac{E_{\mathrm{e}}}{E_{\mathrm{o}}} \tan A \tag{16}
\end{equation*}
$$

are satisfied. From equations (14) we see that

$$
\begin{equation*}
\frac{E_{\mathrm{e}}}{E_{\mathrm{o}}}=\frac{t_{\mathrm{o}}^{\prime} \tan C+t_{\mathrm{c}}^{\prime} \tan (P-C)}{t_{\mathrm{o}}^{\prime}-t_{\mathrm{c}}^{\prime} \tan C \tan (P-C)} \equiv \tan (C+D) \tag{17}
\end{equation*}
$$

where $D=D_{\mathrm{r}}+\mathrm{i} D_{\mathrm{i}}$ is a complex angle defined by

$$
\begin{equation*}
\tan D=\frac{t_{\mathrm{e}}^{\prime}}{t_{\mathrm{o}}^{\prime}} \tan (P-C) \tag{18}
\end{equation*}
$$

Thus a null setting determines the complex ratio $t_{0} / t_{\mathrm{e}}$ in terms of the compensator transmission amplitude ratio and the angles $P, C$ and $A$ :

$$
\begin{equation*}
t_{0} / t_{\mathrm{c}}=-\tan (C+D) \tan A \tag{19}
\end{equation*}
$$

## 5. Polariser-sample-compensator-analyser

This ellipsometer arrangement is as in the previous section, except that the compensator follows the sample. We resolve first along the sample $o$ and e directions. As in section 3, the $o$ and e components of the field after passing through the sample are $t_{\mathrm{o}} \cos P$ and $t_{\mathrm{e}} \sin P$. We now resolve along the $\mathrm{o}^{\prime}$ and $\mathrm{e}^{\prime}$ directions of the compensator. The electric field components are

$$
\left.\begin{array}{l}
E_{\mathrm{o}}^{\prime}=t_{\mathrm{o}} \cos P \cos C+t_{\mathrm{e}} \sin P \sin C  \tag{20}\\
E_{\mathrm{c}}^{\prime}=-t_{\mathrm{o}} \cos P \sin C+t_{\mathrm{e}} \sin P \cos C
\end{array}\right\}
$$

After passing through the compensator the $o^{\prime}$ and $\mathrm{e}^{\prime}$ components are $t_{\mathrm{o}}^{\prime} E_{\mathrm{o}}^{\prime}$ and $t_{\mathrm{e}}^{\prime} E_{\mathrm{c}}^{\prime}$. After the analyser the field (along the analyser easy direction) is

$$
\begin{equation*}
t_{0}^{\prime} E_{\mathrm{o}}^{\prime} \cos (A-C)+t_{\mathrm{c}}^{\prime} E_{\mathrm{e}}^{\prime} \sin (A-C) \tag{21}
\end{equation*}
$$

We again define a complex angle related to the ratio $t_{\mathrm{c}}^{\prime} / t_{\mathrm{o}}^{\prime}$ :

$$
\begin{equation*}
\tan D^{\prime}=\frac{t_{c}^{\prime}}{t_{0}^{\prime}} \tan (A-C) \tag{22}
\end{equation*}
$$

A null setting is obtained when

$$
\begin{equation*}
\frac{E_{0}^{\prime}}{E_{\mathrm{c}}^{\prime}}=-\tan D^{\prime} \tag{23}
\end{equation*}
$$

which gives the complex ratio $t_{\mathrm{o}} / t_{\mathrm{e}}$ in terms of the compensator transmission amplitude ratio and the angles $P, C$ and $A$ :

$$
\begin{equation*}
\frac{t_{0}}{t_{\mathrm{o}}}=-\tan P \tan \left(C+D^{\prime}\right) \tag{24}
\end{equation*}
$$

## 6. Polarizer-modulator-sample-analyser

We now turn to polarization modulation ellipsometry, which has been extensively used in reflection studies of interfaces (Jasperson and Schnatterly 1969, Beaglehole 1980). The use of a birefringence modulator to determine the polarization properties of light has been described in detail by Badoz et al (1977). The polarization state of the light is varied sinusoidally, with synchronous (lock-in) detection of the intensity. The modulator may be, for example, a block of fused quartz glued to a similar block of crystalline quartz, to which is applied an oscillatory electric field. The piezoelectric stress produces an oscillatory birefringence in the fused quartz, which then acts as a modulator with an oscillatory phaseshift

$$
\begin{equation*}
\frac{t_{\mathrm{e}}^{\prime}}{t_{\mathrm{o}}^{\prime}} \approx \mathrm{e}^{\mathrm{i} \delta} \quad \delta(t) \approx M \sin \Omega t \tag{25}
\end{equation*}
$$

Here $M$ is the maximum phaseshift, and $\Omega / 2 \pi$ is the modulation frequency. The first equality in (25) is approximate, since the ratio $t_{\mathrm{e}}^{*} / t_{0}^{\prime}$ does not have unit modulus exactly, as noted in the discussion at the end of section 2 . For most birefringent modulators $\left|t_{\mathrm{e}}^{\prime} / t_{0}^{\prime}\right|$ is very close to unity, and we set it equal to unity for simplicity. The second equality in (25) is also approximate, as has been shown by Acher et al (1988), who considered the effect of residual strain in the modulator, and of higher harmonics in the modulation. Again, we assume (25) to be true here.

Since the modulator is a compensator with a sinusoidally varying phase, we can use part of the analysis of section 5 , making the substitution (25). The field passing the analyser has amplitude given by (14) and (15), which we write as
$t_{\mathrm{o}}^{\prime} t_{\mathrm{e}} \cos (P-C) \cos C \cos A\left\{\tau+\tan C \tan A+\mathrm{e}^{\mathrm{i} \delta} \tan (P-C)[\tan A-\tau \tan C]\right\}$
where

$$
\begin{equation*}
t_{\mathrm{o}} / t_{\mathrm{e}}=\tau=\tau_{\mathrm{r}}+\mathrm{i} \tau_{\mathrm{i}} \tag{27}
\end{equation*}
$$

is the quantity to be determined. The absolute square of the expression inside the braces in equation (26) is

$$
\begin{align*}
\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right)[1+ & \left.\tan ^{2}(P-C) \tan ^{2} C\right]+2 \tau_{\mathrm{r}} \tan C \tan A\left[1-\tan ^{2}(P-C)\right] \\
& +\tan ^{2} A\left[\tan ^{2}(P-C)+\tan ^{2} C\right] \\
& +2 \tau_{\mathrm{j}} \sin \delta \tan (P-C) \tan A\left(1+\tan ^{2} C\right)-2 \cos \delta \tan (P-C) \\
& \times\left\{\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right) \tan C+\tau_{\mathrm{r}} \tan A\left(\tan ^{2} C-1\right)-\tan C \tan ^{2} A\right\} \tag{28}
\end{align*}
$$

Now sinusoidal functions of sinusoidal arguments are periodic, and can thus be expressed as Fourier series, the coefficients of which are Bessel functions (Watson 1966, section 2.22):

$$
\left.\begin{array}{l}
\cos (M \sin \Omega t)=J_{0}(M)+2 \sum_{n=1}^{\infty} J_{2 \mathrm{n}}(M) \cos (2 n \Omega t)  \tag{29}\\
\sin (M \sin \Omega t)=2 \sum_{n=0}^{\infty} J_{2 \mathrm{n}+1}(M) \sin ((2 n+1) \Omega t)
\end{array}\right\}
$$

Thus if we write expression (28) as $a+b \sin \delta+c \cos \delta$, the $\mathrm{DC}, \Omega$ and $2 \Omega$ parts of the intensity are proportional to
$\left.\begin{array}{ll}\mathrm{DC}: & a+c J_{0}(M) \\ \Omega: & \begin{array}{l}2 b J_{1}(M) \sin \Omega t \\ 2 \Omega:\end{array} \\ 2 c J_{2}(M) \cos 2 \Omega t\end{array}\right\}$.
The $\Omega$ signal is proportional to the imaginary part of $t_{0} / t_{\mathrm{e}}$, while the DC and $2 \Omega$ signals depend on both the absolute square and the real part of this ratio.

In considering actual intensities, rather than ratios of intensities, it is better to include the factor $[\cos (P-C) \cos C \cos A]^{2}$ (see expression (26)). The intensity then becomes $\frac{1}{2}\left|t_{0}^{\prime} t_{\mathrm{e}}\right|^{2}\left(a^{\prime}+b^{\prime} \sin \delta+c^{\prime} \cos \delta\right)$, where
$a^{\prime}=\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right) \cos ^{2} A[1+\cos 2(P-C) \cos 2 C]+\tau_{\mathrm{r}} \sin 2 C \sin 2 A \cos 2(P-C)$

$$
\begin{equation*}
+\sin ^{2} A[1-\cos 2(P-C) \cos 2 C] \tag{31}
\end{equation*}
$$

$b^{\prime}=\tau_{\mathrm{i}} \sin 2(P-C) \sin 2 A$
$\left.c^{\prime}=\sin 2(P-C)\left\{\sin 2 C \sin ^{2} A+\tau_{\mathrm{r}} \cos 2 C \sin 2 A-\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right) \sin 2 C\right\} \quad\right\}$
When $P-C=45^{\circ}$ this simplifies to

$$
\left.\begin{array}{l}
a^{\prime}=\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right) \cos ^{2} A+\sin ^{2} A  \tag{32}\\
b^{\prime}=\tau_{\mathrm{i}} \sin 2 A \\
c^{\prime}=\sin 2 C \sin ^{2} A+\tau_{\mathrm{r}} \cos 2 C \sin 2 A-\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right) \sin 2 C
\end{array}\right\}
$$

We note that rotating the sample gives the reference $o$ or e direction by the position at which the $\Omega$ signal is zero, since $b^{\prime}$ is zero when the $o$ or e direction coincides with the analyser easy axis (i.e. when $A=0$ or $90^{\circ}$ ).

## 7. Polarizer-sample-modulator-analyser

The final configuration we consider is a polarization modulation ellipsometer with the modulator between the sample and the analyser. From expressions (20) and (21) of section 5, the field amplitude passing the analyser can be written as

$$
\begin{equation*}
t_{\mathrm{o}}^{\prime} t_{\mathrm{e}} \cos P \cos C \cos (A-C)\left\{\tau+\tan P \tan C+\mathrm{e}^{\mathrm{i} \delta} \tan (A-C)[\tan P-\tau \tan C]\right\} . \tag{33}
\end{equation*}
$$

The absolute square of the quantity inside the braces is

$$
\begin{align*}
\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right)[1+ & \left.\tan ^{2}(A-C) \tan ^{2} C\right]+2 \tau_{\mathrm{r}} \tan P \tan C\left[1-\tan ^{2}(A-C)\right] \\
& +\tan ^{2} P\left[\tan ^{2} C+\tan ^{2}(A-C)\right] \\
& +2 \tau_{\mathrm{i}} \tan P \tan (A-C)\left(1+\tan ^{2} C\right) \sin \delta-2 \tan (A-C) \\
& \times\left\{\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right) \tan C+\tau_{\mathrm{r}} \tan P\left(\tan ^{2} C-1\right)-\tan ^{2} P \tan C\right\} \cos \delta \tag{34}
\end{align*}
$$

If again we write this as $a+b \sin \delta+c \cos \delta$, the $\mathrm{DC}, \Omega$ and $2 \Omega$ signals will be given by expressions (30). Again the $\sin \Omega$ part is proportional to $\tau_{\mathrm{i}}$, while both $\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}$ and $\tau_{r}$ enter into the $D C$ and $\cos 2 \Omega t$ parts. We also note that expression (34) can be obtained from expression (28) by interchanging $A$ and $P$.

The actual intensities are $\frac{1}{2}\left|t_{\mathrm{o}}^{\prime} t_{\mathrm{e}}\right|^{2}\left(a^{\prime}+b^{\prime} \sin \delta+c^{\prime} \cos \delta\right)$, where

$$
\left.\begin{array}{rl}
a^{\prime}= & \left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right) \cos ^{2} P[1+\cos 2(A-C) \cos 2 C]+\tau_{\mathrm{r}} \sin 2 P \sin 2 C \cos 2(A-C) \\
& \quad+\sin ^{2} P[1-\cos 2 C \cos 2(A-C)] \\
b^{\prime}= & \tau_{\mathrm{i}} \sin 2 P \sin 2(A-C) \\
c^{\prime}= & \sin 2(A-C)\left\{\sin ^{2} P \sin 2 C+\tau_{\mathrm{r}} \sin 2 P \cos 2 C-\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{j}}^{2}\right) \sin 2 C\right\}
\end{array}\right\}
$$

When $A-C=45^{\circ}$ the coefficients simplify to

$$
\left.\begin{array}{l}
a^{\prime}=\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right) \cos ^{2} P+\sin ^{2} P  \tag{36}\\
b^{\prime}=\tau_{\mathrm{i}} \sin 2 P \\
c^{\prime}=\sin ^{2} P \sin 2 C+\tau_{\mathrm{r}} \sin 2 P \cos 2 C-\left(\tau_{\mathrm{r}}^{2}+\tau_{\mathrm{i}}^{2}\right) \sin 2 C
\end{array}\right\}
$$

In this case rotating the sample and noting the position at which the $\Omega$ signal is zero gives the $o$ or e direction as then coincident with the easy axis of the polarizer.

## 8. Properties of the transmission ratio $t_{\mathrm{o}} / t_{\mathrm{e}}$

We begin with the simplest case, that of an unsupported crystal plate of thickness $d$. From equations (3) and (4) we have (setting $k_{2}=k_{1}$ )

$$
\begin{equation*}
t_{0}=\frac{4 k_{1} k_{\mathrm{o}} Z_{\mathrm{o}}}{\left(k_{1}+k_{\mathrm{o}}\right)^{2}-\left(k_{1}-k_{\mathrm{o}}\right)^{2} Z_{\mathrm{o}}^{2}} \quad Z_{\mathrm{o}}=\mathrm{e}^{\mathrm{i} \mathrm{k}_{\mathrm{o}} d} . \tag{37}
\end{equation*}
$$

The formula for $t_{\mathrm{e}}$ is obtained by replacing $k_{\mathrm{o}}$ by $k_{\mathrm{e}}$. Thus

$$
\begin{equation*}
\tau=t_{\mathrm{o}} / t_{\mathrm{e}}=\frac{k_{\mathrm{o}} Z_{\mathrm{o}}}{k_{\mathrm{e}} Z_{\mathrm{e}}} \times \frac{\left(k_{1}+k_{\mathrm{e}}\right)^{2}-\left(k_{\mathrm{t}}-k_{\mathrm{e}}\right)^{2} Z_{\mathrm{e}}^{2}}{\left(k_{1}+k_{\mathrm{o}}\right)^{2}-\left(k_{1}-k_{\mathrm{o}}\right)^{2} Z_{\mathrm{o}}^{2}} . \tag{38}
\end{equation*}
$$

The ratio $Z_{\mathrm{o}} / Z_{\mathrm{e}}=\exp \mathrm{i}\left(k_{\mathrm{o}}-k_{\mathrm{e}}\right) d$ gives the phase change which is usually assumed to hold between the $o$ and e waves. For thin crystal plates we set $Z^{2}=1+2 \mathrm{i} k d+\cdots$ (with subscripts o and e), and find that to first order in the plate thickness

$$
\begin{equation*}
\tau=1+\mathrm{i} d\left(k_{\mathrm{o}}-k_{\mathrm{e}}\right)\left(k_{\mathrm{o}}+k_{\mathrm{e}}\right) / 2 k_{1}+\ldots \tag{39}
\end{equation*}
$$

Thus multiple reflections inside the crystal alter the first-order term by the factor $\left(k_{\mathrm{o}}+k_{\mathrm{e}}\right) / 2 k_{1}$. (When the optic axis is perpendicular to the surface normal, this factor equals $\left(n_{\mathrm{o}}+n_{\mathrm{e}}\right) / 2 n_{1}$, which is 1.57 for calcite in air.) For small thicknesses, measurement of the imaginary part of $\tau$ gives the quantity

$$
\begin{equation*}
\left(k_{\mathrm{o}}^{2}-k_{\mathrm{e}}^{2}\right) d / 2 k_{1}=\frac{\pi d}{\lambda_{1}} \times \frac{n_{o}^{2}\left(n_{\mathrm{o}}^{2}-n_{\mathrm{e}}^{2}\right) \sin ^{2} \psi}{n_{\mathrm{o}}^{2} \sin ^{2} \psi+n_{\mathrm{e}}^{2} \cos ^{2} \psi} \tag{40}
\end{equation*}
$$

where $\lambda_{1}$ is the wavelength in the medium of incidence, $\psi$ is the angle between the optic axis and the normal to the crystal plate, and equation (5) has been used.

If we imagine the thickness $d$ of the crystal to increase continuously, $Z_{o}=\mathrm{e}^{\mathrm{i} k_{0} d}$ and $Z_{\mathrm{e}}=\mathrm{e}^{i k_{\mathrm{c}} d}$ move around the unit circle in the complex plane, with periods in $d$ equal to $2 \pi / k_{\mathrm{o}}$ and $2 \pi / k_{\mathrm{e}}$. The transmission amplitude ratio $\tau=t_{\mathrm{o}} / t_{\mathrm{e}}$ also follows a path in the complex plane as $d$ increases. We first consider the behaviour of $\tau$ for thin layers. We can
rewrite equation (38) as

$$
\begin{equation*}
\tau=\frac{t_{\mathrm{o}}}{t_{\mathrm{e}}}=\frac{k_{\mathrm{o}}}{k_{\mathrm{c}}} \times \frac{2 c_{\mathrm{e}} k_{1} k_{\mathrm{e}}-\mathrm{i} \mathrm{~s}_{\mathrm{e}}\left(k_{1}^{2}+k_{\mathrm{e}}^{2}\right)}{2 c_{\mathrm{o}} k_{1} k_{\mathrm{o}}-\mathrm{i} s_{\mathrm{o}}\left(k_{1}^{2}+k_{\mathrm{o}}^{2}\right)} \tag{41}
\end{equation*}
$$

where $c_{\mathrm{o}}=\cos \left(k_{\mathrm{o}} d\right), s_{\mathrm{o}}=\sin \left(k_{\mathrm{o}} d\right)$, and similarly for $c_{\mathrm{e}}$ and $s_{\mathrm{e}}$. Thus the real and imaginary parts of $\tau$ are

$$
\left.\begin{array}{l}
\tau_{\mathrm{r}}=\left(\frac{k_{\mathrm{o}}}{k_{\mathrm{e}}}\right) \frac{4 c_{\mathrm{o}} c_{\mathrm{e}} k_{1}^{2} k_{\mathrm{o}} k_{\mathrm{e}}+s_{\mathrm{o}} s_{\mathrm{e}}\left(k_{1}^{2}+k_{\mathrm{e}}^{2}\right)\left(k_{1}^{2}+k_{\mathrm{o}}^{2}\right)}{4 k_{1}^{2} k_{\mathrm{o}}^{2}+s_{\mathrm{o}}^{2}\left(k_{1}^{2}-k_{\mathrm{o}}^{2}\right)^{2}}  \tag{42}\\
\tau_{\mathrm{i}}=\left(\frac{2 k_{1} k_{\mathrm{o}}}{k_{\mathrm{e}}}\right) \frac{s_{\mathrm{o}} c_{\mathrm{e}} k_{\mathrm{e}}\left(k_{1}^{2}+k_{\mathrm{o}}^{2}\right)-s_{\mathrm{e}} c_{\mathrm{o}} k_{\mathrm{o}}\left(k_{1}^{2}+k_{\mathrm{e}}^{2}\right)}{4 k_{1}^{2} k_{\mathrm{o}}^{2}+s_{\mathrm{o}}^{2}\left(k_{1}^{2}-k_{\mathrm{o}}^{2}\right)^{2}}
\end{array}\right\}
$$

Figure 3 shows how $\tau_{\mathrm{r}}$ and $\tau_{\mathrm{i}}$ vary with crystal thickness, up to about $\frac{1}{4}$ wavelengths. We see that the imaginary part is linear in the thickness only for very thin samples. Both $\tau_{\mathrm{r}}$ and $\tau_{\mathrm{i}}$ are non-monotonic for larger thicknesses, so that a given value of either may not be associated with a unique thickness. We shall see shortly that even when both the real and imaginary parts are measured the thickness is not fixed uniquely.

We now consider the path of $\tau$ in the complex plane as the thickness of the crystal plate increases. From equation (38) we see that $\tau$ is made up of functions with periods $\pi / k_{\mathrm{o}}, \pi / k_{\mathrm{c}}$ and $2 \pi /\left|k_{\mathrm{o}}-k_{\mathrm{e}}\right|$ in the layer thickness $d$. The path of $\tau$ as $d$ increases is like that of a satellite circling a planet which orbits the sun. The motion is not periodic unless $k_{\mathrm{o}} / k_{\mathrm{e}}$ is rational, but $\tau$ crosses the positive real axis each time that $d$ is close to a multiple of $2 \pi /\left|k_{o}-k_{\mathrm{e}}\right|$. We note that the path crosses itself many times during one orbit (see figure 4). At each crossing the same value of $\tau$ results from two nearby values of $d$.

The absolute square of $\tau$ can be written as

$$
\begin{equation*}
|\tau|^{2}=\frac{k_{\mathrm{o}}^{2}}{k_{\mathrm{e}}^{2}} \times \frac{\left(k_{1}^{2}+k_{\mathrm{e}}^{2}\right)^{2}-\left(k_{1}^{2}-k_{\mathrm{e}}^{2}\right)^{2} \cos ^{2}\left(k_{\mathrm{e}} d\right)}{\left(k_{1}^{2}+k_{\mathrm{o}}^{2}\right)^{2}-\left(k_{1}^{2}-k_{\mathrm{o}}^{2}\right)^{2} \cos ^{2}\left(k_{\mathrm{o}} d\right)} . \tag{43}
\end{equation*}
$$

Thus $\tau$ must lie within the annulus formed by two circles centred on the origin:

$$
\begin{equation*}
\frac{2 k_{1} k_{o}}{k_{1}^{2}+k_{o}^{2}} \leqslant|\tau| \leqslant \frac{k_{1}^{2}+k_{e}^{2}}{2 k_{1} k_{e}} \tag{44}
\end{equation*}
$$

Figure 3. The real and imaginary parts of $\tau=t_{0} / t_{\epsilon}$ for a thin calcite layer in air, as a function of the layer thickness. The optic axis is taken to lie parallel to the layer.

Figure 4. The path traced by $\tau=\tau_{\mathrm{o}} / t_{c}$ in the complex plane as the thickness of the anisotropic layer increases from zero to one 'orbital period' $2 \pi / k_{\mathrm{o}}-k_{\mathrm{c}}$. The curve is drawn for calcite, with its optic axis perpendicular to the surface normal. The arrow shows the direction of increasing layer thickness. The real and imaginary axes are each drawn from -1 to +1 . The 'orbit' starts at $\tau=1$ and ends at the point indicated by a dot. The broken curves are the inner and outer bounding circles defined in equation (44).

This spread of values of the magnitude of $\tau$ is attained when its phase is near $\pm \pi / 2$, but a narrower spread occurs when the phase of $\tau$ is close to 0 or $\pi$.

We now consider an anisotropic layer on a substrate of index $n_{2}$ and thickness $d_{2}$. (The discussion following expressions (8) noted that the transmission properties are the same when the light enters the supporting layer first.) The ratio $\tau=t_{\mathrm{o}} / t_{\mathrm{e}}$ is obtained from expressions (7), (8) and the corresponding equations with $k_{\mathrm{e}}$ replacing $k_{0}$. For a thin anisotropic layer the transmission amplitude becomes, to first order in $d$

$$
\begin{equation*}
\tau=1+\frac{\left(k_{\mathrm{o}}^{2}-k_{\mathrm{e}}^{2}\right)\left\{\mathrm{i} k_{1} s_{2}-k_{2} c_{2}\right\} d}{2 \mathrm{i} k_{1} k_{2} c_{2}+\left(k_{1}^{2}+k_{2}^{2}\right) s_{2}}+O\left(d^{2}\right) \tag{45}
\end{equation*}
$$

where $c_{2}=\cos k_{2} d_{2}$ and $s_{2}=\sin k_{2} d_{2}$, as in (8). This expression reduces to (39) when $d_{2} \rightarrow 0$, and also when $k_{2} \rightarrow k_{1}$ (in either case the substrate has no optical effect). Note that, in contrast to (39), the first-order term is complex rather than imaginary. The real and imaginary parts are seen by writing the coefficient of $d$ in (45) as

$$
\begin{equation*}
\left(k_{o}^{2}-k_{\mathrm{e}}^{2}\right) \frac{\left\{\left(k_{1}^{2}-k_{2}^{2}\right) k_{2} s_{2} c_{2}+\mathrm{i}\left[2 k_{2}^{2}+s_{2}^{2}\left(k_{1}^{2}-k_{2}^{2}\right)\right]\right\}}{\left(2 k_{1} k_{2}\right)^{2}+\left(k_{1}^{2}-k_{2}^{2}\right)^{2} s_{2}^{2}} . \tag{46}
\end{equation*}
$$

We see that the real part is zero when $\sin 2 k_{2} d_{2}$ is zero, but that the imaginary part is non-zero for all values of $k_{2} d_{2}$.

The 'substrate' may in fact be a thin isotropic layer (for example a liquid film) supported by the crystal. Thus it is interesting to examine the behaviour of $\tau$ as $d_{2}$ tends to zero. We find that $\tau$ is the sum of (41) plus a series in powers of $d_{2}$, the coefficient of $d_{2}$ being
$\frac{k_{\mathrm{o}}}{k_{\mathrm{e}}} \frac{\left(k_{2}^{2}-k_{1}^{2}\right)\left\{k_{1}^{2}\left(k_{\mathrm{o}} c_{\mathrm{o}} s_{\mathrm{e}}-k_{\mathrm{e}} c_{\mathrm{e}} s_{\mathrm{o}}\right)+k_{\mathrm{o}} k_{\mathrm{e}}\left(k_{\mathrm{o}} s_{\mathrm{o}} c_{\mathrm{e}}-k_{\mathrm{e}} s_{\mathrm{e}} c_{\mathrm{o}}\right)+\mathrm{i}\left(k_{\mathrm{e}}^{2}-k_{\mathrm{o}}^{2}\right) k_{1} s_{\mathrm{o}} s_{\mathrm{e}}\right\}}{\left[\left(k_{1}^{2}+k_{\mathrm{o}}^{2}\right) s_{\mathrm{o}}+2 \mathrm{i} k_{1} k_{\mathrm{o}} c_{\mathrm{o}}\right]^{2}}$.

As one would expect, this becomes zero when the anisotropy tends to zero, and also when $n_{2} \rightarrow n_{1}$.

We comment finally on absorbing media. The fundamental formulae derived here are valid for absorbing crystals and/or substrates. Absorption is allowed for by means of complex values of the dielectric constants $\varepsilon_{0}, \varepsilon_{\mathrm{e}}$ and $\varepsilon_{2}$, or of the refractive indices $n_{\mathrm{o}}$, $n_{\mathrm{e}}$ and $n_{2}$. The wavevectors $k_{\mathrm{o}}, k_{\mathrm{e}}$ and $k_{2}$ will be complex if the media are absorbing. Throughout this paper we have made simplifications based on the tacit assumption that $k_{\mathrm{o}}, k_{\mathrm{e}}$ and $k_{2}$ are real. For example, (41) is general but (42), (43) and (44) assume that the $k s$ are real. Likewise (45) is general but in deducing (46) we have assumed that $k_{2}$ is real.

## Appendix. Normal incidence onto biaxial crystals

When a wave is incident onto any planar stratified system which is invariant with respect to translation along the system surface, the wavevector components parallel to the surface will be conserved. For normal incidence this implies that the wavevector $k$ inside the anisotropic medium will be along the inward surface normal. (The propagation of energy, with direction given by $\boldsymbol{E} \times \boldsymbol{B}$, is not in general along $\boldsymbol{k}$, as is well known.)

To find the possible values of $|\boldsymbol{k}|$ inside a homogeneous anisotropic medium, we eliminate the magnetic field $\boldsymbol{B}$ from the Maxwell curl equations. For plane waves, with space and time dependence $\exp \mathrm{i}(\boldsymbol{k} \cdot \boldsymbol{r}-\omega t)$, these read

$$
\begin{equation*}
k \times E=\frac{\omega}{c} B \quad k \times B=-\frac{\omega}{c} \varepsilon E \tag{A1}
\end{equation*}
$$

where $\varepsilon$ is the dielectric tensor. On eliminating $B$ by taking the vector product of the first equation in (A1) with $k$ and substituting from the second, one obtains (see, for example, Born and Wolf 1965 , section 14.2.1)

$$
\begin{equation*}
\left(\varepsilon \omega^{2} / c^{2}-k^{2}\right) E+k(k \cdot E)=0 \tag{A2}
\end{equation*}
$$

We look at the possible solutions of (A2) in the principal dielectric axes frame, in which

$$
\varepsilon=\left(\begin{array}{ccc}
\varepsilon_{\mathrm{a}} & 0 & 0  \tag{A.3}\\
0 & \varepsilon_{\mathrm{b}} & 0 \\
0 & 0 & \varepsilon_{\mathrm{c}}
\end{array}\right)
$$

The three equations (A2) then read

$$
\left.\begin{array}{l}
\left(\varepsilon_{\mathrm{a}} \omega^{2} / c^{2}-k^{2}\right) E_{\mathrm{a}}+k_{\mathrm{a}}\left(k_{\mathrm{a}} E_{\mathrm{a}}+k_{\mathrm{b}} E_{\mathrm{b}}+k_{c} E_{\mathrm{c}}\right)=0  \tag{A4}\\
\left(\varepsilon_{\mathrm{b}} \omega^{2} / c^{2}-k^{2}\right) E_{\mathrm{b}}+k_{\mathrm{b}}\left(k_{\mathrm{a}} E_{\mathrm{a}}+k_{\mathrm{b}} E_{\mathrm{b}}+k_{\mathrm{c}} E_{\mathrm{c}}\right)=0 \\
\left(\varepsilon_{\mathrm{c}} \omega^{2} / c^{2}-k^{2}\right) E_{\mathrm{c}}+k_{\mathrm{c}}\left(k_{\mathrm{a}} E_{\mathrm{a}}+k_{\mathrm{b}} E_{\mathrm{b}}+k_{\mathrm{c}} E_{\mathrm{c}}\right)=0
\end{array}\right\} .
$$

This is a set of three homogeneous equations in the unknowns $E_{\mathrm{a}}, E_{\mathrm{b}}$ and $E_{\mathrm{c}}$, and a solution with non-zero $E$ exists if the determinant of the coefficients of $E_{\mathrm{a}}, E_{\mathrm{b}}$ and $E_{\mathrm{c}}$ is zero. This leads to 'Fresnel's equation of wave normals' (Born and Wolf 1965,
section 14.2.2), which we write in the form

$$
\begin{align*}
\left(\alpha^{2} \varepsilon_{\mathrm{a}}+\beta^{2} \varepsilon_{\mathrm{b}}+\right. & \left.\gamma^{2} \varepsilon_{\mathrm{c}}\right)\left(\frac{c k}{\omega}\right)^{4}-\left\{\left(\alpha^{2}+\beta^{2}\right) \varepsilon_{\mathrm{a}} \varepsilon_{\mathrm{b}}+\left(\beta^{2}+\gamma^{2}\right) \varepsilon_{\mathrm{b}} \varepsilon_{\mathrm{c}}+\left(\gamma^{2}+\alpha^{2}\right) \varepsilon_{\mathrm{c}} \varepsilon_{\mathrm{a}}\right\}\left(\frac{c k}{\omega}\right)^{2} \\
& +\varepsilon_{\mathrm{a}} \varepsilon_{\mathrm{b}} \varepsilon_{\mathrm{c}}=0 \tag{A5}
\end{align*}
$$

where $\alpha, \beta$ and $\gamma$ are the direction cosines of $k$ relative to the principal dielectric axes $\boldsymbol{a}, \boldsymbol{b}$ and $\boldsymbol{c}$, so that

$$
\begin{equation*}
k=k(\alpha, \beta, \gamma) \quad \alpha^{2}+\beta^{2}+\gamma^{2}=1 \tag{A6}
\end{equation*}
$$

Equation (A5) is a quadratic in $k^{2}$, giving the magnitude of the wavevector as a function of its direction. We label the solutions $k_{ \pm}^{2}$, according to the sign chosen in taking the square root of the discriminant of equation (A.5). We will note some properties of the solutions. Suppose (as is conventional) the axes are chosen so that

$$
\begin{equation*}
\varepsilon_{\mathrm{a}} \leqslant \varepsilon_{\mathrm{b}} \leqslant \varepsilon_{\mathrm{c}} . \tag{A7}
\end{equation*}
$$

Then bounds on $k_{ \pm}^{2}$ are

$$
\begin{equation*}
\varepsilon_{\mathrm{a}} \leqslant\left(\frac{c k_{-}}{\omega}\right)^{2} \leqslant \varepsilon_{\mathrm{b}} \quad \varepsilon_{\mathrm{b}} \leqslant\left(\frac{c k_{+}}{\omega}\right)^{2} \leqslant \varepsilon_{\mathrm{c}} \tag{A8}
\end{equation*}
$$

Equality in (A8) is attained when $k$ is parallel or perpendicular to one of the dielectric axes. When $\alpha^{2}=1$, for example, $(c k / \omega)^{2}$ takes the values $\varepsilon_{b}$ and $\varepsilon_{\mathrm{c}}$, while when $\alpha=0$ it takes the values $\varepsilon_{\mathrm{a}}$ and $\varepsilon_{\mathrm{b}} \varepsilon_{\mathrm{c}} /\left(\beta^{2} \varepsilon_{\mathrm{b}}+\gamma^{2} \varepsilon_{\mathrm{c}}\right)$.

The discriminant of the quadratic for $(c k / \omega)^{2}$ can be written as

$$
\begin{align*}
\alpha^{4} \varepsilon_{\mathrm{a}}^{2}\left(\varepsilon_{\mathrm{b}}-\varepsilon_{\mathrm{c}}\right)^{2} & +\beta^{4} \varepsilon_{\mathrm{b}}^{2}\left(\varepsilon_{\mathrm{c}}-\varepsilon_{\mathrm{a}}\right)^{2}+\gamma^{4} \varepsilon_{\mathrm{c}}^{2}\left(\varepsilon_{\mathrm{a}}-\varepsilon_{\mathrm{b}}\right)^{2}+2 \alpha^{2} \beta^{2} \varepsilon_{\mathrm{a}} \varepsilon_{\mathrm{b}}\left(\varepsilon_{\mathrm{c}}-\varepsilon_{\mathrm{a}}\right)\left(\varepsilon_{\mathrm{c}}-\varepsilon_{\mathrm{b}}\right) \\
& +2 \beta^{2} \gamma^{2} \varepsilon_{\mathrm{b}} \varepsilon_{\mathrm{c}}\left(\varepsilon_{\mathrm{a}}-\varepsilon_{\mathrm{b}}\right)\left(\varepsilon_{\mathrm{a}}-\varepsilon_{\mathrm{c}}\right)+2 \gamma^{2} \alpha^{2} \varepsilon_{\mathrm{c}} \varepsilon_{\mathrm{a}}\left(\varepsilon_{\mathrm{b}}-\varepsilon_{\mathrm{c}}\right)\left(\varepsilon_{\mathrm{b}}-\varepsilon_{\mathrm{a}}\right) \tag{A9}
\end{align*}
$$

From inequality (A7), all the terms are non-negative except for the last. When $k$ is perpendicular to the $b$ axis ( $\beta=0$ ), three of the non-negative terms are zero, and the negative term remains. Thus the minimum of the discriminant occurs when $\beta=0$, its value then being

$$
\begin{equation*}
\left\{\alpha^{2} \varepsilon_{\mathrm{a}}\left(\varepsilon_{\mathrm{c}}-\varepsilon_{\mathrm{b}}\right)-\gamma^{2} \varepsilon_{\mathrm{c}}\left(\varepsilon_{\mathrm{b}}-\varepsilon_{\mathrm{a}}\right)\right\}^{2} \tag{A10}
\end{equation*}
$$

The discriminant is thus zero when the direction cosines $\alpha, \beta, \gamma$ of $k$ are given by

$$
\begin{equation*}
\alpha^{2}=\frac{\varepsilon_{c}\left(\varepsilon_{b}-\varepsilon_{a}\right)}{\varepsilon_{b}\left(\varepsilon_{c}-\varepsilon_{a}\right)} \quad \beta=0 \quad \gamma^{2}=\frac{\varepsilon_{a}\left(\varepsilon_{c}-\varepsilon_{b}\right)}{\varepsilon_{b}\left(\varepsilon_{c}-\varepsilon_{a}\right)} \tag{A11}
\end{equation*}
$$

Thus there are four directions of $k$, given by equations (A11), for which the discriminant is zero and the roots $k_{ \pm}^{2}$ of equation (A5) are equal. These directions, by definition, determine the two optic axes, along which the phase speeds of the two modes are equal ( $k$ and $-k$ are taken to be equivalent in the definition of optic axes). The common eigenvalue of equation (A5) when equations (A11) hold is $k^{2}=\varepsilon_{b} \omega^{2} / c^{2}$. Note that the optic axes lie in the $a, c$ plane, and have directions $(|\alpha|, 0, \pm|\gamma|)$, where $\alpha^{2}$ and $\gamma^{2}$ are
given by equations (A11). The cosine of the angle between the optic axes is therefore

$$
\begin{equation*}
\frac{\varepsilon_{\mathrm{a}} \varepsilon_{\mathrm{b}}+\varepsilon_{\mathrm{b}} \varepsilon_{\mathrm{e}}-2 \varepsilon_{\mathrm{c}} \varepsilon_{\mathrm{a}}}{\varepsilon_{\mathrm{b}}\left(\varepsilon_{\mathrm{c}}-\varepsilon_{\mathrm{a}}\right)} \tag{A12}
\end{equation*}
$$

Thus the principal dielectric axis a is the acute bisectrix of the optic axes if $\varepsilon_{\mathrm{b}}$ is greater than the harmonic mean of $\varepsilon_{\mathrm{a}}$ and $\varepsilon_{\mathrm{c}}$.

Once equation (A5) is solved for the magnitude of $k$, the direction of the corresponding electric field vector can be found from (A2):

$$
\begin{equation*}
E_{\mathrm{a}}=\frac{k_{\mathrm{a}}(k \cdot E)}{k^{2}-\varepsilon_{\mathrm{a}} \omega^{2} / c^{2}} \quad \text { etc. } \tag{A13}
\end{equation*}
$$

Thus, for given direction $(\alpha, \beta, \gamma)$ of $\boldsymbol{k}$, the electric field components are in the ratio

$$
\begin{equation*}
E_{\mathrm{a}}: E_{\mathrm{b}}: E_{\mathrm{c}}=\frac{\alpha}{(c k / \omega)^{2}-\varepsilon_{\mathrm{a}}}: \frac{\beta}{(c k / \omega)^{2}-\varepsilon_{\mathrm{b}}}: \frac{\gamma}{(c k / \omega)^{2}-\varepsilon_{\mathrm{c}}} \tag{A14}
\end{equation*}
$$

where $k^{2}$ is one of the solutions $k_{+}^{2}, k_{-}^{2}$ of equation (A5). (In the cases where one or more of the denominators in equation (A14) is zero, the directions of $E$ must be found directly from expression (A2), to avoid division by zero in equation (A13).)
$E^{+}$and $E^{-}$are not orthogonal in general, but we will prove that their projections onto the reflecting surface are orthogonal. To verify this we show that, for normal incidence,

$$
\begin{equation*}
\left(n \times E^{+}\right) \cdot\left(n \times E^{-}\right)=0 \tag{A15}
\end{equation*}
$$

where $n$ is the inward surface normal. This is the same as the unit vector in the $k$ direction, i.e. $n=(\alpha, \beta, \gamma)$, so

$$
\begin{equation*}
n \times E=\left(\beta E_{\mathrm{c}}-\gamma E_{\mathrm{b}}, \gamma E_{\mathrm{a}}-\alpha E_{\mathrm{c}}, \alpha E_{\mathrm{b}}-\beta E_{\mathrm{a}}\right) \tag{A16}
\end{equation*}
$$

From equation (A14), this is proportional to the vector
$\beta \gamma\left(\varepsilon_{\mathrm{b}}-\varepsilon_{\mathrm{c}}\right)\left[\varepsilon_{\mathrm{a}}-(c k / \omega)^{2}\right], \gamma \alpha\left(\varepsilon_{\mathrm{c}}-\varepsilon_{\mathrm{a}}\right)\left[\varepsilon_{\mathrm{b}}-(c k / \omega)^{2}\right], \alpha \beta\left(\varepsilon_{\mathrm{a}}-\varepsilon_{\mathrm{b}}\right)\left[\varepsilon_{\mathrm{c}}-(c k / \omega)^{2}\right]$.
Thus the scalar product in equation (A15) is the cyclic sum of terms like

$$
\begin{equation*}
\beta^{2} \gamma^{2}\left(\varepsilon_{\mathrm{b}}-\varepsilon_{\mathrm{c}}\right)^{2}\left(\varepsilon_{\mathrm{a}}-\varepsilon_{+}\right)\left(\varepsilon_{\mathrm{a}}-\varepsilon_{-}\right) \tag{A18}
\end{equation*}
$$

where $\varepsilon_{ \pm}=\left(c k_{ \pm} / \omega\right)^{2}$ are the solutions of equation (A5). The quadratic equation (A5), of the form

$$
\begin{equation*}
A(c k / \omega)^{3}+B(c k / \omega)^{2}+C=0 \tag{A19}
\end{equation*}
$$

has solutions $\varepsilon_{+}$and $\varepsilon_{\text {_ }}$ whose product and sum are given by

$$
\begin{equation*}
\varepsilon_{+} \varepsilon_{-}=C / A \quad \varepsilon_{+}+\varepsilon_{-}=-B / A \tag{A20}
\end{equation*}
$$

Thus the product of the final two terms in (A18) is equal to

$$
\begin{equation*}
\left(A \varepsilon_{\mathrm{a}}^{2}+B \varepsilon_{\mathrm{a}}+C\right) / A \tag{A21}
\end{equation*}
$$

On using $\alpha^{2}+\beta^{2}+\gamma^{2}=1$ and the values of $A, B$ and $C$ as given in (A5), it follows from the algebraic identity

$$
\begin{equation*}
\beta^{2} \gamma^{2}\left(\varepsilon_{\mathrm{b}}-\varepsilon_{\mathrm{c}}\right)^{2}\left(A \varepsilon_{\mathrm{a}}^{2}+B \varepsilon_{\mathrm{a}}+C\right)+\text { cyclic terms }=0 \tag{A22}
\end{equation*}
$$

that the projections of $\boldsymbol{E}^{+}$and $\boldsymbol{E}^{-}$onto the plane perpendicular to $\boldsymbol{n}$ are orthogonal. Thus, at normal incidence, biaxial crystals have both modes with wavevector normal to the surface, of magnitudes $k_{+}$and $k_{-}$, and electric field components in the plane of the surface are orthogonal. The continuity of the tangential components of $E$ and of their derivatives at the boundaries of the crystal, which determines the reflection and transmission amplitudes, can thus be applied to biaxial crystals in the same way as to uniaxial crystals.

We note finally that the vector identity

$$
\begin{equation*}
(a \times b) \cdot(c \times d)=(a \cdot c)(b \cdot d)-(a \cdot d)(b \cdot c) \tag{A23}
\end{equation*}
$$

applied to (A15) shows that at normal incidence

$$
\begin{equation*}
E^{+} \cdot E^{-}=\left(n \cdot E^{+}\right)\left(n \cdot E^{-}\right) \tag{A24}
\end{equation*}
$$

That is, the scalar product of the two electric fields is equal to the product of the components of $E^{+}$and $E^{-}$along the direction of propagation.

## Acknowledgment

The author is grateful to Professor David Beaglehole for suggesting this problem, and for stimulating discussions.
